Global characteristic problem for the Einstein vacuum equations with small initial data: (II) The existence proof.

Giulio Caciotta Francesco Nicolò *†
Università degli studi di Roma "Tor Vergata"

February 7, 2008

Abstract

This is the second part of our result on a class of global characteristic problems for the Einstein vacuum equations with small initial data. In the previous work, [Ca-Ni1], denoted by (I), our attention was focused on prescribing the initial data satisfying the costraints imposed by the characteristic problem. Here we show how the global existence result can be achieved. This part is heavily based on the global results of D.Christodoulou, S.Klainerman, [Ch-Kl], and S.Klainerman, F.Nicolò, [Kl-Ni].

†Part of this research was done at the Isaac Newton Institute for Mathematical Sciences (Cambridge University), during the semester program "Global Problems in Mathematical Relativity" organized by P.Chrusciel, H.Friedrich, P.Tod.

1 Introduction

This is the second paper on the solution of a global characteristic problem for the Einstein vacuum equations with small data. In the first one, hereafter denoted with (I), we examined the way of posing the initial data on the initial null hypersurfaces, their constraints and their connection with the initial data given in the harmonic background. Here we show how we can prove an existence result using a strategy which mimics the one used to prove the global stability of the Minkowski spacetime, [Ch-Kl], [Kl-Ni].

2 The global existence theorem, strategy of the proof.

In this section we state the global existence theorem and describe the main steps of its proof. The following sections are devoted to their implementations.

2.1 Statement of the characteristic global existence theorem.

Theorem 2.1 (characteristic global existence theorem) *Let the initial hypersurface be the union of two null truncated cones $C_0 \cup \underline{C}_0$, see figure* 1*, let the initial data* [1]

$$\left\{C_0 \ ; \overline{\gamma}_{ab}, \overline{\Omega}, \overline{\zeta}_a, \underline{\overline{\chi}}_{ab}, \underline{\overline{\omega}}\right\} \cup \left\{\underline{C}_0 \ ; \overline{\gamma}_{ab}, \underline{\overline{\Omega}}, \underline{\overline{X}}^a \overline{\zeta}_a, \overline{\chi}_{ab}, \overline{\omega}\right\} \tag{2.1}$$

be assigned together with their partial tangential derivatives to a fixed order specified by the integer $q \geq 7$. Let us assume they satisfy the smallness conditions:

$$J^{(q)}_{C_0 \cup \underline{C}_0} = J^{(q)}_{C_0}\left[\overline{\gamma}_{ab}, \overline{\Omega}, \overline{\zeta}^a, \underline{\overline{\chi}}, \underline{\overline{\omega}}\right] + J^{(q)}_{\underline{C}_0}\left[\overline{\gamma}_{ab}, \underline{\overline{\Omega}}, \overline{\zeta}_a, \overline{\chi}, \overline{\omega}\right] \leq \varepsilon \ , \tag{2.2}$$

where $J^{(q)}_{C_0}$ and $J^{(q)}_{\underline{C}_0}$ are defined in (I), (I;3.17), (I;3.18)*. Assume, moreover, that the initial data are such that on $S_0 = C_0 \cap \underline{C}_0$, the following estimates for the Riemann null components hold,* [2]

$$\begin{aligned} &|r_0^{(\frac{7}{2}+\delta)-\frac{2}{p}}\beta|_{p,S_0} \leq c\varepsilon \ , \ |r_0^{(3+\delta)-\frac{2}{p}}(\rho-\overline{\rho},\sigma)|_{p,S_0} \leq c\varepsilon \\ &|r_0^{3-\frac{2}{p}}\rho|_{p,S_0} \leq c\varepsilon \ , \ |r_0^{(2+\delta)-\frac{2}{p}}\underline{\beta}|_{p,S_0} \leq c\varepsilon \ , \end{aligned} \tag{2.3}$$

where $r_0^2 = (4\pi)^{-1}|S_0|$. Then there exists a unique vacuum Einstein spacetime, $(\mathcal{M}, \mathbf{g})$, solving the characteristic initial value problem with initial data 2.1. $\mathcal{M}$

[1] The null "cones" and the various quantities which describe the initial data have been defined in(I), section 1.3.

[2] In (I) it is shown that this condition follows immediately once some bounds for $\gamma, \chi, \underline{\chi}, \zeta$ on S_0 are satisfied, see (I), Proposition 2.11 equations (2.91).

is the maximal future Cauchy development of $C(\lambda_1) \cup \underline{C}(\nu_0)$,[3]

$$\mathcal{M} = \lim_{\nu_1 \to \infty} \mathcal{M}(\nu_1) = \lim_{\nu_1 \to \infty} J^+(S(\lambda_1, \nu_0)) \cap J^-(S(\lambda_0, \nu_1)) \ . \tag{2.4}$$

Moreover $\mathcal{M}$ *is endowed with the following structures:*

a) $\mathcal{M}$ *is foliated by a "double null canonical foliation"* $\{C(\lambda)\}$, $\{\underline{C}(\nu)\}$, *with* $\lambda \in [\lambda_1, \lambda_0]$, $\nu \in [\nu_0, \infty)$.[4] *Double canonical foliation means that the null hypersurfaces* $C(\lambda)$ *are the level hypersurfaces of a function* $u(p)$ *solution of the eikonal equation*

$$g^{\mu\nu} \partial_\mu w \partial_\nu w = 0 \ ,$$

with initial data a specific function $u_*(p)$ *defining the foliation of the "final" incoming cone,*[5] *while the the null hypersurfaces* $\underline{C}(\nu)$ *are the level hypersurfaces of a function* $\underline{u}(p)$ *solution of the eikonal equation with initial data a specific function* $\underline{u}_{(0)}(p)$ *defining the foliation of the initial outgoing cone* $C(\lambda_1)$.[6] *The family of two dimensional surfaces* $\{S(\lambda, \nu)\}$, *where* $S(\lambda, \nu) \equiv C(\lambda) \cap \underline{C}(\nu)$, *defines a two dimensional foliation of* $\mathcal{M}$.

b) $i(C_0) = C(\lambda_1)$, $i(\underline{C}_0) = \underline{C}(\nu_0)$, $i(S_0(\nu_0)) = i(\underline{S}_0(\lambda_1)) = C(\lambda_1) \cap \underline{C}(\nu_0)$.

c) On $C(\lambda_1)$ *with respect to the initial data foliation,*[7] *we have*

$$\begin{aligned} &i^*(\gamma') = \overline{\gamma} \ , \ i^*(\Omega') = \overline{\Omega} \ , \ {i_*}^{-1}(X') = \overline{X} \\ &i^*(\chi') = \overline{\chi} \ , \ i^*(\omega') = \overline{\omega} \ , \ i^*(\zeta') = \overline{\zeta} \end{aligned} \tag{2.5}$$

together with their tangential derivatives up to q.

d) On $\underline{C}(\nu_0)$ *with respect to the initial data foliation, we have*

$$\begin{aligned} &i^*(\gamma') = \overline{\gamma} \ , \ i^*(\Omega') = \overline{\underline{\Omega}}, \ {i_*}^{-1}(\underline{X}') = \overline{\underline{X}} \\ &i^*(\underline{\chi}') = \overline{\underline{\chi}} \ , \ i^*(\underline{\omega}') = \overline{\underline{\omega}} \ , \ i^*(\zeta') = \overline{\zeta} \end{aligned} \tag{2.6}$$

[3] Sometimes to avoid any confusion we write explicitely $C(\lambda_1; [\nu_0, \infty)) \cup \underline{C}(\nu_0; [\lambda_1, \lambda_0])$. $\mathcal{M}(\nu_1)$ is the maximal Cauchy development of $C(\lambda_1; [\nu_0, \nu_1]) \cup \underline{C}(\nu_0; [\lambda_1, \lambda_0])$. $C(\lambda_1)$ and $\underline{C}(\nu_0)$, the images in $\mathcal{M}$ of C_0 and $\underline{C}_0$ respectively, are explicitely defined in b).

[4] recall that with "double canonical foliation" we refer to a foliation of the spacetime $(\mathcal{M}, \mathbf{g})$, while with "canonical foliation" we denote a specific foliation of the initial data on C_0. Of course the first one is related to the second.

[5] The function $u_*(p)$ is the limit as $\nu_1 \to \infty$ of a function $u_*(\nu_1; p)$ defined on $\underline{C}(\nu_1; [\lambda_1, \lambda_0])$. A detailed discussion of this limit is in [Kl-Ni], Chapter 8.

[6] We require that $\underline{u}_{(0)}(p)$ defines on $C(\lambda_1)$ a canonical foliation. In the characteristic case this is not really needed. This is due to the fact that, as we will discuss later on, the regularity of the initial data is higher than that of the same quantities in $\mathcal{M}$. We can, nevertheless, require it and, in this case, it is important to remark that the "canonical" foliation of $C(\lambda_1)$ is not the one given when the initial data are specified, see (I). It can be proved that, given the initial data foliation of $C(\lambda_1)$, it is possible to build on $C(\lambda_1)$ a "canonical" one. Its precise definition and the way for doing it is discussed in [Kl-Ni], Chapter 3 and with more details in [Ni1].

[7] Observe that while $\mathcal{M}$ is globally foliated by a double null canonical foliation, it is not possible to foliate it with a double foliation solution of the eikonal equation with as initial data the Ω-foliation of C_0 and $\underline{C}_0$. This is, nevertheless possible in a small neighbourhood of C_0 and $\underline{C}_0$.

where $\gamma', \Omega', X', \chi', \underline{\chi}', \omega', \underline{\omega}', \zeta'$ *are the metric components and the connection coefficients in a neighbourhood of* $C(\lambda_1)$ *and* $\underline{C}(\nu_0)$.[8]

e) The costraint equations (I;1.55),(I;1.56) *are the pull back of (some of) the structure equations of* $\mathcal{M}$ *restricted to* $C(\lambda_1)$ *and* $\underline{C}(\nu_0)$.[9]

f) Let the double null canonical foliation and the associated two dimensional one, $\{S(\lambda,\nu)\}$ *be given. We can define on the whole* $\mathcal{M}$ *a null orthonormal frame* $\{e_4, e_3, e_a\}$ *adapted to it, the metric components,* γ_{ab}, Ω, X^a *with respect to the adapted coordinates* $\{u, \underline{u}, \theta, \phi\}$[10] *and the corresponding connection coefficients*

$$\begin{aligned}
\chi_{ab} &= \mathbf{g}(\mathbf{D}_{e_a} e_4, e_b) \ , \ \underline{\chi}_{ab} = \mathbf{g}(\mathbf{D}_{e_a} e_3, e_b) \\
\underline{\omega} &= \frac{1}{4}\mathbf{g}(\mathbf{D}_{e_3} e_3, e_4) = -\frac{1}{2}\mathbf{D}_3(\log\Omega) \\
\omega &= \frac{1}{4}\mathbf{g}(\mathbf{D}_{e_4} e_4, e_3) = -\frac{1}{2}\mathbf{D}_4(\log\Omega) \\
\zeta_a &= \frac{1}{2}\mathbf{g}(\mathbf{D}_{e_a} e_4, e_3) \ .
\end{aligned} \tag{2.7}$$

Moreover X^a *is a vector field defined in* $\mathcal{M}$ *such that denoting* N *and* $\underline{N}$ *two null vector fields equivariant with respects to the* $S(\lambda,\nu)$ *surfaces, the following relations hold:* $N = \Omega e_4$, $\underline{N} = \Omega e_3$ *and in the* $\{u, \underline{u}, \theta, \phi\}$ *coordinates*

$$N = 2\Omega^2 \frac{\partial}{\partial \underline{u}} \ , \ \underline{N} = 2\Omega^2 \left(\frac{\partial}{\partial u} + X^a \frac{\partial}{\partial \omega^a} \right) \ .$$

g) The null geodesics of $\mathcal{M}$ *along the outgoing and incoming null direction* e_4, e_3 *are defined for all* $\nu \in [\nu_0, \infty)$ *and all* $\lambda \in [\lambda_1, \lambda_0]$ *respectively. Finally the existence result is uniform in* $\lambda_1 (< 0)$.[11]

2.2 The general structure of the proof.

The proof is made by two different parts whose structure is, basically, the same.

First part: We prove the existence of the spacetime

$$\mathcal{M}' = J^+(S(\lambda_1, \nu_0)) \cap J^-(S(\lambda_0, \nu_1)) \ ,$$

where, see figure 2,[12] $\qquad 2\rho_0 = \nu_0 - \lambda_1 = \nu_1 - \lambda_0$.

[8] These quantities denoted here $\gamma', \Omega', \ldots\ldots$ were denoted in (I) $\gamma, \Omega, \underline{\Omega}, X, \underline{X}, \chi, \underline{\chi}, \omega, \underline{\omega}, \zeta$. In the sequel these notations will be referred to the corresponding quantities relative to the double canonical foliation of $\mathcal{M}$ and their restrictions to $C_0 \cup \underline{C}_0$.

[9] With respect to the foliations of the initial data.

[10] The precise way the coordinate θ and ϕ are defined will be discussed elsewhere. See also [Kl-Ni], paragraph 3.1.6.

[11] This means that the quantities 2.2, depending on the initial data, which we require to be small are independent from λ_1.

[12] All the null hypersurfaces are represented as if the spacetime $\mathcal{M}$ were flat.

Second part: We prove the existence of the spacetime $\mathcal{M} \supset \mathcal{M}'$,

$$\mathcal{M} = \lim_{\nu_1 \to \infty} J^+(S(\lambda_1, \nu_0)) \cap J^-(S(\lambda_0, \nu_1)) \ ,$$

see figure 3.

Remark: It is appropriate at this point to present an intuitive picture of the spacetime we are building. As our result is a small data result we expect that our spacetime stays near to (a portion of) the Minkowski spacetime. This implies that the functions $\underline{u}(p)$ and $u(p)$ do not differ much, written in spherical Minkowski coordinates, from $t + r$ and $t - r$, respectively. Moreover the radius $r(\lambda, \nu)$ defined as $(4\pi)^{-\frac{1}{2}}$ times the square root of the area of $S(\lambda, \nu)$, see *(I;2.13)*, will stay near the r spherical coordinate. The initial cones C_0 and $\underline{C}_0$ approximate two truncated minkowskian cones, one outgoing and one incoming, with their vertices on the origin vertical axis. The assumption that ν_0 and $|\lambda_1|$ are approximately equal to r_0 just pictures the two dimensional surface S_0 as lying (approximately) on the hyperplane $t = 0$ where t is "near" to $\frac{1}{2}(\underline{u} + u)$.[13]

Proof of the first part: We denote $(\mathcal{K}(\tau), \mathbf{g})$ a solution of the "characteristic Cauchy problem" with the following properties:

i) $(\mathcal{K}(\tau), \mathbf{g})$ is foliated by a double null canonical foliation $\{C(\lambda)\}$, $\{\underline{C}(\nu)\}$ with $\lambda \in [\lambda_1, \overline{\lambda}]$, $\nu \in [\nu_0, \overline{\nu}]$. Moreover

$$i(C_0) \cap \mathcal{K}(\tau) = C(\lambda_1; [\nu_0, \overline{\nu}]) \ ; \ i(\underline{C}_0) \cap \mathcal{K}(\tau) = \underline{C}(\nu_0; [\lambda_1, \overline{\lambda}])$$

where [14]

$$\overline{\nu} + \overline{\lambda} = 2\tau \quad ; \quad \overline{\nu} - \overline{\lambda} = 2\rho_0 \ . \tag{2.8}$$

ii) Denoted $\{e_3, e_4, e_a\}$ the null orthonormal frame adapted to the double null canonical foliation. We introduce a family of norms $\mathcal{R}, \mathcal{O}$ for the null components of the Riemann curvature tensor and for the connection coefficients respectively, as done in [Kl-Ni], Chapter 3.

iii) Given $\epsilon_0 > 0$ sufficiently small, but larger than ε, the norms $\mathcal{R}, \mathcal{O}$ satisfy the following inequalities

$$\mathcal{R} \leq \epsilon_0 \ , \ \mathcal{O} \leq \epsilon_0 \ . \tag{2.9}$$

iv) Denoted by $\mathcal{T}$ the set of all values τ for which the spacetime $\mathcal{K}(\tau)$ does exist, we define τ_* as the sup over all the values of $\tau \in \mathcal{T}$, see figure 4:

$$\tau_* = \sup\{\tau \in \mathcal{T}\} \ . \tag{2.10}$$

[13] Although the picture defined here is the more natural, with a redefinition of the functions $\underline{u}, u, r$ in terms of the standard coordinates one could also treat in a similar way the case where the two "initial" cones C_0 and $\underline{C}_0$ are shifted one respect to the other and their vertices do not lie even approximatley on the same vertical axis.

[14] As the spacetime we obtain is "near" to a portion of the Minkowski spacetime, condition 2.8 can be visualized as the requirement that $S(\overline{\lambda}, \overline{\nu})$ coincides with a vertical (time) translation of S_0.

There are, now, two possibilities:

$$\tau_* = \lambda_0 + \rho_0 \quad \text{or} \quad \tau_* < \lambda_0 + \rho_0 \ . \tag{2.11}$$

If $\tau_* = \lambda_0 + \rho_0$ then

$$\mathcal{K}(\tau_*) = J^+(S(\lambda_1, \nu_0)) \cap J^-(S(\lambda_0, \nu_1)) \tag{2.12}$$

and the first part is proved. If, viceversa, $\tau_* < \lambda_0 + \rho_0$, we show that in $\mathcal{K}(\tau_*)$ the norms $\mathcal{R}$ and $\mathcal{O}$ satisfy the following estimates

$$\mathcal{R} \leq \frac{1}{2}\epsilon_0 \ \ ; \ \ \mathcal{O} \leq \frac{1}{2}\epsilon_0 \ . \tag{2.13}$$

v) Using the inequalities 2.13 restricted to $\underline{C}(\nu_*)$ it is possible to prove that we can extend the spacetime $\mathcal{K}(\tau_*)$ to a spacetime $\mathcal{K}(\tau_* + \delta)$. This contradicts the fact that τ_* is the supremum defined in 2.10, unless $\tau_* = \lambda_0 + \rho_0$. In fact in this case $\mathcal{K}(\tau_*)$ describes the maximal region $\mathcal{K}(\tau)$ which can be determined from the initial conditions assigned on $\underline{C}(\nu_0; [\lambda_1, \lambda_0]) \cup C(\lambda_1; [\nu_0, \nu_1])$ even if $\mathcal{R} \leq \frac{1}{2}\epsilon_0; \ \mathcal{O} \leq \frac{1}{2}\epsilon_0$.

vi) Due to the fact, which will be evident in the course of the proof, that the estimates for $\mathcal{R}$ and $\mathcal{O}$ do not depend on the magnitude of the interval $[\lambda_1, \lambda_0]$, also the proof of the first part can be considered a global existence result. In other words fixed λ_0, we can choose $\rho_0 = \frac{1}{2}(\nu_0 - \lambda_1)$ arbitrarily large which implies that also $\tau_* = \lambda_0 + \rho_0$ can be chosen arbitrarily large.

In conclusion the result of the first part is achieved if we prove that:

i) The set $\mathcal{T}$ is not empty.

ii) In $\mathcal{K}(\tau_*)$ the norms $\mathcal{R}$ and $\mathcal{O}$ satisfy the following estimates

$$\mathcal{R} \leq \frac{1}{2}\epsilon_0 \ \ ; \ \ \mathcal{O} \leq \frac{1}{2}\epsilon_0 \ . \tag{2.14}$$

iii) If $\tau_* < \lambda_0 + \rho_0$ we can extend $\mathcal{K}(\tau_*)$ to $\mathcal{K}(\tau_* + \delta)$ with $\delta > 0$.

Steps i), ii) and iii) are the technical parts of the result. Their detailed proofs are in the subsequent sections.

Proof of the second part: It is, basically, a corollary of the proof of the first part. We consider in this case the spacetimes $\mathcal{M}(\overline{\nu})$ solutions of the "characteristic Cauchy problem" (or the "characteristic canonical Cauchy problem") with the following properties:

i) $(\mathcal{M}(\nu), \mathbf{g})$ is foliated by a double null canonical foliation $\{C(\lambda)\}$, $\{\underline{C}(\nu)\}$ with $\lambda \in [\lambda_1, \lambda_0]$, $\nu \in [\nu_0, \overline{\nu}]$. Moreover

$$i(C_0) \cap \mathcal{M}(\overline{\nu}) = C(\lambda; [\nu_0, \overline{\nu}]) \ ; \ i(\underline{C}_0) \cap \mathcal{M}(\overline{\nu}) = \underline{C}(\nu_0; [\lambda_1, \lambda_0])$$

ii) let $\{e_3, e_4, e_a\}$ be the null orthonormal frame adapted to the double null canonical foliation, defined as in [Kl-Ni], Chapter 3. We introduce a family of

norms $\mathcal{R}, \mathcal{O}$ for the connection coefficients and for the null components of the Riemann curvature tensor respectively, as done in [Kl-Ni], Chapter 3.

iii) Given $\epsilon_0 > 0$ sufficiently small, but larger than ε, the norms $\mathcal{R}, \mathcal{O}$ satisfy the following inequalities

$$\mathcal{R} \leq \epsilon_0 \ , \ \mathcal{O} \leq \epsilon_0 \ . \tag{2.15}$$

iv) Let $\mathcal{N}$ be the set of all values $\overline{\nu}$ for which the spacetime $\mathcal{M}(\overline{\nu})$ does exist. We define ν_* as the sup over all the values of $\overline{\nu} \in \mathcal{N}$, see figure 5:

$$\nu_* = \sup\{\overline{\nu} \in \mathcal{N}\} \ . \tag{2.16}$$

Again there are two possibilities: if $\nu_* = \infty$ the result is achieved, therefore we are left to show that the second possibility, $\nu_* < \infty$, leads to a contradiction. For it we show first that in $\mathcal{M}(\nu_*)$ the norms $\mathcal{R}$ and $\mathcal{O}$ satisfy the following estimates

$$\mathcal{R} \leq \frac{1}{2}\epsilon_0 \ ; \ \mathcal{O} \leq \frac{1}{2}\epsilon_0 \ . \tag{2.17}$$

v) Using inequalities 2.17 restricted to $\underline{C}(\nu_*; [\lambda_1, \lambda_0])$, it is possible to prove that we can extend the spacetime $\mathcal{M}(\nu_*)$ to a spacetime $\mathcal{M}(\nu_* + \delta)$, a fact which contradicts the definition of ν_* unless $\nu_* = \infty$.

Remark: Observe that in the second part of the proof we do not have to show that the set $\mathcal{N}$ is not empty as, due to the first part of the proof, $\mathcal{N}$ contains, at least, the element $\overline{\nu} = \lambda_0 + 2\rho_0$.

2.3 A broad sketch of the technical parts of the proof.

First part:

i) To prove that the set $\mathcal{T}$ is not empty we have to show that a spacetime $\mathcal{K}(\tau)$ exists, possibly with small τ. This requires a local existence theorem and we can borrow it from the results of A.Rendall, [Ren] or of H.Muller Zum Hagen, H.Muller Zum Hagen and H.J.Seifert, [Mu], [Mu-Se]. The main difficulty in adapting these results to the present case is that they are proved using harmonic coordinates while the "gauge" we use for $\mathcal{K}(\tau)$ is the one associated to the double null canonical foliation. This requires a precise connection between the initial data written in the two different gauges in such a way that we can reexpress their results in our formalism. This will be discussed in a next section.

ii) Once we have proved that $\mathcal{T}$ is not empty we can define $\mathcal{K}(\tau_*)$ and prove that in this spacetime inequalities 2.13,

$$\mathcal{R} \leq \frac{1}{2}\epsilon_0 \ ; \ \mathcal{O} \leq \frac{1}{2}\epsilon_0 \ ,$$

hold. This requires, see [Kl-Ni], Chapter 3 for a detailed discussion, that the double null foliation of $\mathcal{K}(\tau_*)$ be canonical which, at its turn, requires to prove the existence of specific foliations, denoted again "canonical", on $C(\lambda_1)$ and on

$\underline{C}(\nu_*)$. These "canonical" foliations will play the role of the "initial data" for the solutions of the eikonal equations

$$g^{\mu\nu}\partial_\mu w \partial_\nu w = 0$$

whose level hypersurfaces define the double null canonical foliation $\{C(\lambda)\}$, $\{\underline{C}(\nu)\}$ of $\mathcal{K}(\tau_*)$, see also [Ni1].[15]

iii) The central part of the proof consists in showing that we can extend $\mathcal{K}(\tau_*)$ to $\mathcal{K}(\tau_* + \delta)$ with $\delta > 0$, see figure 6.

To achieve it we have to implement the following steps:

1) First of all we have to prove an existence theorem for the strips $\Delta_1\mathcal{K}$, $\Delta_2\mathcal{K}$,

$$\begin{aligned} \Delta_1\mathcal{K} &= J^+(S(\lambda_1, \nu_*) \cap J^-(S(\overline{\lambda}(\nu_*), \nu_* + \delta)) \\ \Delta_2\mathcal{K} &= J^+(S(\overline{\lambda}(\nu_*), \nu_0) \cap J^-(S(\overline{\lambda}(\nu_* + \delta), \nu_*)) \ , \end{aligned} \tag{2.18}$$

where, see 2.11,[16]

$$\overline{\lambda}(\nu) = -2\rho_0 + \nu \ . \tag{2.19}$$

and whose boundaries are:

$$\begin{aligned} \partial\Delta_1\mathcal{K} \ = \ & C(\lambda_1; [\nu_*, \nu_* + \delta]) \cup \underline{C}(\nu_* + \delta; [\lambda_1, \overline{\lambda}(\nu_*)]) \\ & \cup C(\overline{\lambda}(\nu_*); [\nu_*, \nu_* + \delta]) \cup \underline{C}(\nu_*; [\lambda_1, \overline{\lambda}(\nu_*)]) \end{aligned} \tag{2.20}$$

$$\begin{aligned} \partial\Delta_2\mathcal{K} \ = \ & \underline{C}(\nu_0; [\overline{\lambda}(\nu_*), \overline{\lambda}(\nu_* + \delta)]) \cup C(\overline{\lambda}(\nu_* + \delta); [\nu_0, \nu_*]) \\ & \cup \underline{C}(\nu_*; [\overline{\lambda}(\nu_*), \overline{\lambda}(\nu_* + \delta)]) \cup C(\overline{\lambda}(\nu_*); [\nu_0, \nu_*]) \ , \end{aligned} \tag{2.21}$$

2) We are then left with proving the (local) existence of a diamond shaped region,

$$\Delta_3\mathcal{K} = J^+(S(\overline{\lambda}(\nu_*), \nu_*) \cap J^-(S(\overline{\lambda}(\nu_* + \delta), \nu_* + \delta)) \ , \tag{2.22}$$

specified by the initial data

$$C(\overline{\lambda}(\nu_*); [\nu_*, \nu_* + \delta]) \cup \underline{C}(\nu_*; [\overline{\lambda}(\nu_*), \overline{\lambda}(\nu_* + \delta)]) \ . \tag{2.23}$$

3) Finally on the portion of the boundary of

$$\mathcal{K}(\tau_* + \delta) = \mathcal{K}(\tau_*) \cup \Delta_1\mathcal{K} \cup \Delta_2\mathcal{K} \cup \Delta_3\mathcal{K} \ ,$$

[15] The existence of this foliation has to be proved also for the (local) spacetime of i). The proof one gives for $\mathcal{K}(\tau_*)$ can be easily adapted to this case. The canonical foliation is crucial to obtain on $\underline{C}(\nu_*)$ all the connection coefficients, to be used again as initial data for the backward transport equations, without any loss of derivatives.

[16] From 2.11 and 2.19 it follows that $\lambda_0 - \overline{\lambda}(\nu_*) \geq 0$.

made by $\underline{C}(\nu_* + \delta; [\lambda_1, \overline{\lambda}(\nu_* + \delta))])$ [17] a new canonical foliation has to be constructed which stays "near" to the (non canonical) foliation obtained extending the double null canonical foliation of $\mathcal{K}(\tau_*)$ up to $\underline{C}(\nu_* + \delta; [\lambda_1, \overline{\lambda}(\nu_* + \delta))])$ which will be considered, in this case, as the background foliation.
This completes the description of all the steps needed to prove our result. The detailed proof will be given in the following sections.

Second part:

In this case, as already said, we know that the set $\mathcal{N}$ is not empty. To prove that $\nu_* = \infty$ we have to show that, if ν_* were finite, the spacetime $\mathcal{M}(\nu_*)$ could be extended to a spacetime $\mathcal{M}(\nu_* + \delta)$ with the same properties. To prove it we need an existence theorem for the strip, see figure 5,

$$\Delta\mathcal{M} = J^+(S(\lambda_1, \nu_*)) \cap J^-(S(\lambda_0, \nu_* + \delta)) \ .$$

As in the case of $\Delta_1\mathcal{K}$ and $\Delta_2\mathcal{K}$, this existence theorem is a non local result as the "length" of the strip does not have to be small in the e_3 direction. Therefore also in this case the proof requires a bootstrap mechanism.
Finally, as at the end of the proof of the first part, we have to show that $\mathcal{M}(\nu_* + \delta)$ can be endowed with a double canonical foliation whose existence can be proved once we prove the existence of a canonical foliation on the "last slice", $\underline{C}(\nu_* + \delta; [\lambda_1, \lambda_0])$, see [Kl-Ni] Chapter 3 and [Ni1].

Remark: One has to keep in mind that moving from $\mathcal{K}(\tau_*)$ to $\mathcal{K}(\tau_* + \delta)$ the double null canonical foliation of $\mathcal{K}(\tau_* + \delta)$ is different from to the one associated to $\mathcal{K}(\tau_*)$. The difference is in the outgoing cones $\{C(\lambda)\}$. In fact the ingoing cones $\{\underline{C}(\nu)\}$ of $\mathcal{K}(\tau_* + \delta)$ are just the extension (in λ) of those already present in $\mathcal{K}(\tau_*)$, as they are the level surfaces of the function $\underline{u}(p)$ solution of the eikonal equation with initial data on $C(\lambda_1)$ (associated to its canonical foliation). The situation is different for the outgoing cones $\{C(\lambda)\}$. They are also the level hypersurfaces of a solution $u(p)$ of the eikonal equation, but this time the initial data are associated to the canonical foliation of the upper boundary, $\underline{C}(\nu_*)$ and $\underline{C}(\nu_* + \delta)$ respectively. Therefore the outgoing cones of the double null canonical foliation of $\mathcal{K}(\tau_* + \delta)$ are not an extension of the corresponding ones of $\mathcal{K}(\tau_*)$. Nevertheless it can be proved easily that they differ from the previous ones by a quantity[18] which is small and does not depend on the length of the cones, see for instance [Kl-Ni] Chapter 8.

3 Technical parts of the existence proof

As it will be clear in the course of the proof, the whole program to be completed requires a local existence proof for the characteristic problem; this is somewhat a separate step which can be done in many ways, therefore we state only the result we need and postpone the discussion of it to a subsequent section.

[17] The canonical foliation on $C(\lambda_1; [\nu_0, \nu_* + \delta])$ was already proved and it does not change.

[18] To be precise we have to define a quantity describing the nearness of the two families of cones, for instance one can define it as the sup of the oscillation of the new function $u(p)$ along the previous $S(\lambda, \nu)$.

3.1 Local existence result

In the proof of our result a bootstrap argument is used many times. Each time to implement it a local existence result is needed. We show that all these local results are of the same type.
The first time a local existence is needed is when we prove that the set $\mathcal{T}$ is not empty. This requires that, possibly for small $\overline{\tau}$, a (portion of) spacetime, $\mathcal{K}(\overline{\tau})$ must exist, satisfying the properties i),...,vi) given at the beginning of subsection 2.2. This follows from an existence proof for a characteristic Cauchy problem with initial data on the union of two null hypersurfaces, one corresponding to an "outgoing cone", $C(\lambda_1)$ and the other one to an incoming cone $\underline{C}(\nu_0)$, intersecting along the two dimensional surface $S_0 = S(\lambda_1, \nu_0)$.
The region $\mathcal{K}(\overline{\tau})$ must be, given $\overline{\tau} = \frac{1}{2}(\overline{\nu}+\overline{\lambda})$, the maximal Cauchy development associated to the initial null hypersurface $\mathcal{C}_{\overline{\tau}} = C(\lambda_1; [\nu_0, \overline{\nu}]) \cup \underline{C}(\nu_0; [\lambda_1, \overline{\lambda}])$. Therefore the boundary of $\mathcal{K}(\overline{\tau})$ will be:

$$\partial\mathcal{K}(\overline{\tau}) = C(\lambda_1; [\nu_0, \overline{\nu}]) \cup \underline{C}(\nu_0; [\lambda_1, \overline{\lambda}]) \cup \underline{C}(\overline{\nu}; [\lambda_1, \overline{\lambda}]) \cup C(\overline{\lambda}; [\nu_0, \overline{\nu}]) \qquad (3.1)$$

with $\overline{\lambda}, \overline{\nu}$ satisfying $\quad \overline{\nu} - \overline{\lambda} = 2\rho_0$.
In the local existence proof the initial data norms on $\mathcal{C}_{\overline{\tau}}$ must be sufficiently small, $\leq \varepsilon$, so that the corresponding norms on $\underline{C}(\overline{\nu}; [\lambda_1, \overline{\lambda}]) \cup C(\overline{\lambda}; [\nu_0, \overline{\nu}])$ are bounded by $c\varepsilon$ with ε such that $c\varepsilon \leq \epsilon_0$.
Once this result is proved the set $\mathcal{T}$ is not empty and we can define $\mathcal{K}(\tau_*)$. Next step consists in showing that the region $\mathcal{K}(\tau_*)$ can be extended to a larger region $\mathcal{K}(\tau_*+\delta)$ endowed with the same properties. As discussed in the following subsections this requires proving the existence of the slab $\Delta_1\mathcal{K} \cup \Delta_2\mathcal{K} \cup \Delta_3\mathcal{K}$.
Let us consider first the portion $\Delta_1\mathcal{K}$. As discussed in subsection 3.3, to prove its existence a bootstrap argument is required. Again this requires a local existence result with initial data on the null hypersurface $\mathcal{C}_1 = C(\lambda_1; [\overline{\nu}, \overline{\nu}+\delta]) \cup \underline{C}(\overline{\nu}; [\lambda_1, \lambda_1 - \delta])$, whose norms are bounded by $c_1\varepsilon$. The same local existence proof is required for the region $\Delta_2\mathcal{K}$ and finally, if δ is sufficiently small, a local existence proof is enough to prove the existence of the region $\Delta_3\mathcal{K}$.
The conclusion is that the various local existence results we need are always of the same type which can be summarized in the following theorem:

Theorem 3.1 (Local existence result) *Let the initial data*

$$\left\{C_{in}\ ; \overline{\gamma}_{ab}, \overline{\Omega}, \overline{\zeta}_a, \underline{\chi}_{ab}, \underline{\omega}\right\} \cup \left\{\underline{C}_{in}\ ; \overline{\gamma}_{ab}, \underline{\Omega}, \overline{X}^a \overline{\zeta}_a, \overline{\chi}_{ab}, \overline{\omega}\right\} \qquad (3.2)$$

be assigned together with their partial tangential derivatives to a fixed order specified by the integer $q \geq 7$. Let us assume they satisfy the smallness conditions:

$$J^{(q)}_{C_{in} \cup \underline{C}_{in}} = J^{(q)}_{C_{in}}\left[\overline{\gamma}_{ab}, \overline{\Omega}, \overline{\zeta}^a, \underline{\chi}, \underline{\omega}\right] + J^{(q)}_{\underline{C}_{in}}\left[\overline{\gamma}_{ab}, \underline{\Omega}, \overline{\zeta}_a, \overline{\chi}, \overline{\omega}\right] \leq \varepsilon\ , \qquad (3.3)$$

where $J^{(q)}_{C_{in}}$ and $J^{(q)}_{\underline{C}_{in}}$ are defined as $J^{(q)}_{C_0}$ and $J^{(q)}_{\underline{C}_0}$ in (I), (I;3.17) , (I;3.18). *Then there exists a couple $(\lambda_{fin}, \nu_{fin})$ satisfying*

$$\nu_{fin} - \lambda_{fin} = 2\overline{\rho} \quad , \quad \nu_{fin} + \lambda_{fin} = 2\overline{\tau}\ \ ,$$

with $\overline{\tau} = \tau_{in} + \overline{\sigma}$, with $\overline{\sigma}$ a positive number, possibly small, such that a vacuum Einstein spacetime, $(\mathcal{K}(\overline{\tau}), \mathbf{g})$ exists, the maximal future development of $C(\lambda_{in}; [\nu_{in}, \nu_{fin}]) \cup \underline{C}(\nu_{in}; [\lambda_{in}, \lambda_{fin}])$,

$$\mathcal{K}(\overline{\tau}) = J^+(S(\lambda_{in}, \nu_{in})) \cap J^-(S(\lambda_{fin}, \nu_{fin})) \ . \tag{3.4}$$

$C(\lambda_{in}; [\nu_{in}, \nu_{fin}]) \cup \underline{C}(\nu_{in}; [\lambda_{in}, \lambda_{fin}])$ is the image, relative to an immersion i, of a portion of the initial data null hypersurface $\mathcal{C}_{in} = C_{in} \cup \underline{C}_{in}$ and the couple (λ_{in}, ν_{in}) satisfies:

$$\nu_{in} - \lambda_{in} = 2\overline{\rho} \quad , \quad \nu_{in} + \lambda_{in} = 2\tau_{in} \ .$$

Moreover $\mathcal{K}(\overline{\tau})$ can be endowed with the following structures:

a) A "double null canonical foliation" $\{C(\lambda; [\nu_{in}, \nu_{fin}])\}$, $\{\underline{C}(\nu; [\lambda_{in}, \lambda_{fin}])\}$, with $\lambda \in [\lambda_{in}, \lambda_{fin}]$, $\nu \in [\nu_{in}, \nu_{fin}]$. The family of two dimensional surfaces $\{S(\lambda, \nu)\}$, where $S(\lambda, \nu) \equiv C(\lambda; [\nu_{in}, \nu_{fin}]) \cap \underline{C}(\nu; [\lambda_{in}, \lambda_{fin}])$, defines a two dimensional foliation of $\mathcal{K}(\overline{\tau})$.

b) On $C(\lambda_{in}; [\nu_{in}, \nu_{fin}])$ with respect to the initial data foliation, we have

$$\begin{aligned} &i^*(\gamma') = \overline{\gamma} \ , \ i^*(\Omega') = \overline{\Omega} \ , \ {i_*}^{-1}(X') = \overline{X} \\ &i^*(\chi') = \overline{\chi} \ , \ i^*(\omega') = \overline{\omega} \ , \ i^*(\zeta') = \overline{\zeta} \end{aligned} \tag{3.5}$$

together with their tangential derivatives up to q.

c) On $\underline{C}(\nu_{in}; [\lambda_{in}, \lambda_{fin}])$ with respect to the initial data foliation, we have

$$\begin{aligned} &i^*(\gamma') = \overline{\gamma} \ , \ i^*(\Omega') = \overline{\underline{\Omega}}, \ {i_*}^{-1}(\underline{X}') = \overline{\underline{X}} \\ &i^*(\underline{\chi}') = \overline{\underline{\chi}} \ , \ i^*(\underline{\omega}') = \overline{\underline{\omega}} \ , \ i^*(\zeta') = \overline{\zeta} \end{aligned} \tag{3.6}$$

where $\gamma', \Omega', X', \chi', \underline{\chi}', \omega', \underline{\omega}', \zeta'$ are the metric components and the connection coefficients in a neighbourhood of $C(\lambda_{in}; [\nu_{in}, \nu_{fin}])$ and $\underline{C}(\nu_{in}; [\lambda_{in}, \lambda_{fin}])$.

d) The costraint equations (I;1.55),(I;1.56) *are the pull back of (some of) the structure equations of $\mathcal{K}(\overline{\tau})$ restricted to $C(\lambda_{in}; [\nu_{in}, \nu_{fin}])$ and $\underline{C}(\nu_{in}; [\lambda_{in}, \lambda_{fin}])$.*

e) It is possible to define on $\mathcal{K}(\overline{\tau})$ a null orthonormal frame $\{e_4, e_3, e_a\}$ adapted to the "double null canonical foliation", the metric components, γ_{ab}, Ω, X^a with respect to the adapted coordinates $\{u, \underline{u}, \theta, \phi\}$ and the corresponding connection coefficients

$$\begin{aligned} \chi_{ab} &= \mathbf{g}(\mathbf{D}_{e_a} e_4, e_b) \ , \ \underline{\chi}_{ab} = \mathbf{g}(\mathbf{D}_{e_a} e_3, e_b) \\ \underline{\omega} &= -\frac{1}{2}\mathbf{D}_3(\log\Omega) \ , \ \omega = -\frac{1}{2}\mathbf{D}_4(\log\Omega) \\ \zeta_a &= \frac{1}{2}\mathbf{g}(\mathbf{D}_{e_a} e_4, e_3) \ . \end{aligned} \tag{3.7}$$

Moreover a vector field X^a can be defined in $\mathcal{K}(\overline{\tau})$ such that denoting N and $\underline{N}$ two null vector fields equivariant with respect to the $S(\lambda, \nu)$ surfaces, the following relations hold: $N = \Omega e_4$, $\underline{N} = \Omega e_3$ and, in the $\{u, \underline{u}, \theta, \phi\}$ coordinates,

$$N = 2\Omega^2 \frac{\partial}{\partial \underline{u}} \ , \ \underline{N} = 2\Omega^2 \left(\frac{\partial}{\partial u} + X^a \frac{\partial}{\partial \omega^a} \right) \ .$$

Remarks:

a) The structure of the local existence theorem which we will use repeatedly in the following, is the same as that of the first part of the "characteristic global existence theorem", Theorem 2.1. The basic difference is that in Theorem 2.1, the region $\mathcal{K}(\tau_*)$ is the maximal development of the initial data characteristic hypersurface $C(\lambda_1;[\nu_0,\nu_1])\cup\underline{C}(\nu_0;[\lambda_1,\lambda_0])$ and τ_* is not small.

b) The subsets of the regions $\Delta_1\mathcal{K},\Delta_2\mathcal{K},\Delta_3\mathcal{K}$ whose existence is proved by the local existence result, correspond to different values of λ_{in} and ν_{in}, namely [19]

$$\Delta_1^{loc}\mathcal{K}:\lambda_{in}=\lambda_1\ ,\ \nu_{in}=\overline{\nu}\ ,\ \lambda_{fin}=\lambda_{in}-\delta'\ ,\ \nu_{fin}=\nu_{in}+\delta'$$
$$\Delta_2^{loc}\mathcal{K}:\lambda_{in}=\lambda_0\ ,\ \nu_{in}=\nu_0\ ,\ \lambda_{fin}=\lambda_{in}-\delta''\ ,\ \nu_{fin}=\nu_{in}+\delta''$$
$$\Delta_3^{loc}\mathcal{K}:\lambda_{in}=\overline{\lambda}(\nu_*)\ ,\ \nu_{in}=\nu_*\ ,\ \lambda_{fin}=\lambda_{in}-\delta'''\ ,\ \nu_{fin}=\nu_{in}+\delta'''\ .$$

c) The initial data for the region $\Delta_1\mathcal{K}$ are given on the initial null hypersurfaces $C(\lambda_1;[\nu_*,\nu_*+\delta])\cup\underline{C}(\nu_*;[\lambda_1,\lambda_0])$ therefore a part of them are (a portion of) the initial data of the initial problem, those on $\underline{C}(\nu_*;[\lambda_1,\lambda_0])$ are provided by the values that the various connection coefficients and their derivatives acquire on the upper boundary of the region $\mathcal{K}(\tau_*)$. Also these data are small as follows from the control of the $\mathcal{O}$ norms in this region, see subsection 3.2. Moreover as the initial data are expressed in terms of the connection coefficients, see (I), they automatically satisfy the constraints equations of the characteristic problem. Exactly the same argument holds for $\Delta_2\mathcal{K}$, while for $\Delta_3\mathcal{K}$ the initial data for extending our result to this region are obtained after the construction of regions $\Delta_1\mathcal{K}$ and $\Delta_2\mathcal{K}$ is completed.

d) The proof of the local existence result will not be given in this paper as, basically, it already exists due to A.Rendall, [Ren], D.Christodoulou and H.Muller Zum Hagen, [Ch-Mu], [Mu]. Nevertheless as their proof is given in the harmonic gauge we have to connect the initial data norms we use in this paper with those defined in the harmonic gauge. This connection has been discussed at length in section 4 of (I) and we recall some aspects of it in Section 5. There we also examine the local existence proof in [Ch-Mu], [Mu] and give some hints for a different proof using a Cauchy-Kowalevski type argument, [Ni2].

3.2 Better norm estimates in $\mathcal{K}(\tau_*)$

This is the first step required to prove our result. This is also the more difficult one, but in the present case is a repetition of part of the proof given in [Kl-Ni], Chapters 4-5-6. The main difference is in the nature of the initial data given here on two null hypersurfaces. Nevertheless even when the data are assigned, proving the result presents some differences and some simplifications.

a) Due to the nature of the initial hypersurfaces, a problem present in [Kl-Ni] is not present. There, in fact, once a double null canonical foliation was obtained, it was possible to define a global time function, $t(p)=\frac{1}{2}(u(p)+\underline{u}(p))$

[19] The final value δ will be the smallest between δ',δ'',δ'''.

and prove that the two dimensional surfaces $S(\lambda,\nu) = C(\lambda) \cap \underline{C}(\nu)$ were embedded in the spacelike hypersurfaces, Σ_t, level surfaces of the time function. The problem was that these spacelike hypersurfaces were not maximal and, as $t \to 0$, they did not coincide with the (spacelike) initial data hypersurface. This required a delicate control of a small slab near Σ_0 to show how the initial data could be transported along the outgoing and incoming cones, See [Kl-Ni] section 4.1.3 . In the present case this problem is completely avoided as the two initial data null hypersurfaces belong to the double null canonical foliation.

b) The second difference, but not a simplification, is that, as discussed in (I, subsubsection 3.1.3), a greater regularity for the initial data along the directions "S-tangential"[20] to the initial null hypersurfaces, is needed to have a sufficient control of the initial data derivatives in the direction "orthogonal" to them. This higher regularity is needed only for the initial data and, contrarily to what said in (I), a control of higher derivatives in the region $\mathcal{K}(\nu_*)$ is not needed. This discussion can be summarized in the following theorem:

Theorem 3.2 *Let $(\mathcal{K}(\tau), \mathbf{g})$ be a solution of the "characteristic Cauchy problem" relative to initial data* [21] *satisfying $J^{(q)}_{C_0 \cup \underline{C}_0} \leq \varepsilon$ and inequalities 2.3, with the following properties:*

i) *$(\mathcal{K}(\tau), \mathbf{g})$ is foliated by a double null canonical foliation $\{C(\lambda)\}$, $\{\underline{C}(\nu)\}$ with $\lambda \in [\lambda_1, \overline{\lambda}]$, $\nu \in [\nu_0, \overline{\nu}]$. Moreover*

$$i(C_0) \cap \mathcal{K}(\tau) = C(\lambda_1; [\nu_0, \overline{\nu}]) \ ; \ i(\underline{C}_0) \cap \mathcal{K}(\tau) = \underline{C}(\nu_0; [\lambda_1, \overline{\lambda}])$$
$$\text{where} \qquad \overline{\nu} + \overline{\lambda} = 2\tau \qquad ; \qquad \overline{\nu} - \overline{\lambda} = 2\rho_0 \ .$$

ii) *Let $\{e_3, e_4, e_a\}$ be a null orthonormal frame adapted to the double null canonical foliation. Let $\mathcal{R}, \mathcal{O}$ be the family of norms for the null components of the Riemann curvature tensor and for the connection coefficients relative to this null frame, given in [Kl-Ni], Chapter 3. Given $\epsilon_0 > 0$ sufficiently small, but larger than ε, assume that the norms $\mathcal{R}, \mathcal{O}$ satisfy the following inequalities*

$$\mathcal{R} \leq \epsilon_0 \quad , \quad \mathcal{O} \leq \epsilon_0 \ . \tag{3.8}$$

iii) *Denoted by $\mathcal{T}$ the set of all values τ for which the spacetime $\mathcal{K}(\tau)$ does exist, we define τ_* as the* sup *over all the values of $\tau \in \mathcal{T}$:*

$$\tau_* = \sup\{\tau \in \mathcal{T}\} \ . \tag{3.9}$$

Under all these assumptions it follows that in $\mathcal{K}(\tau)$ these norms satisfy the bounds

$$\mathcal{R} \leq c\varepsilon \quad , \quad \mathcal{O} \leq c\varepsilon \ , \tag{3.10}$$

an improvement of 3.8, if ε is chosen sufficiently small.

[20] The directions tangential to the two dimensional surfaces $S(\lambda_1, \nu)$ and $S(\lambda, \nu_0)$.

[21] More precisely the portion of initial data on $C(\lambda_1; [\nu_0, \overline{\nu}]) \cup \underline{C}(\nu_0; [\lambda_1, \overline{\lambda}])$.

Proof: The theorem is a repetition of a set of theorems proved in [Kl-Ni], more specifically Theorems M1, M2, M3, M4, M5, M7, M8. The main difference is that the norms $\mathcal{O}$ and $\mathcal{R}$ relative to the initial data, contains more $\nabla\!\!\!/$-derivatives than those required in [Kl-Ni]. We specify the chosen order of derivatives for the initial data norms in Section 3.4.

3.3 Existence proof for the strips $\Delta_1\mathcal{K}$, $\Delta_2\mathcal{K}$ and the diamond $\Delta_3\mathcal{K}$

3.3.1 $\Delta_1\mathcal{K}$, $\Delta_2\mathcal{K}$

The first observation is that proving the existence of the strip $\Delta_1\mathcal{K}$ amounts to prove again a "global" existence result. In fact this strip, although very narrow in the outgoing future direction (δ can be chosen as small as we like), has a length, measured with the affine parameter λ, which can be arbitrarily large. Recall that the "length" of $\Delta_1\mathcal{K}$, $|\overline{\lambda}(\nu_*) - \lambda_1|$, depends linearily on ν_*, see equation 2.19, and that ν_* can be arbitrary large depending on the choice of ρ_0, see equation 2.8.
This is a somewhat delicate point. First of all we observe that the existence proof for the strip $\Delta_1\mathcal{K}$ is significantly different from the analogous step in the non characteristic result of [Ch-Kl]. In fact in that case the spacetime is foliated by spacelike hypersurfaces $\{\Sigma_t\}$ and going from Σ_{t_*} to $\Sigma_{t_*+\delta}$ is a purely local existence result while in the present case the strip $\Delta_1\mathcal{K}$ extends toward the future (in time) for a possibly very large interval. This could seem, at first sight, a serious problem as to prove the existence of the maximal Cauchy development associated to the initial data, that is of the unbounded spacetime region with boundary $C(\lambda_1) \cup \underline{C}(\nu_0; [\lambda_1, \lambda_0]) \cup C(\lambda_0)$, we need to prove preliminary the existence of the (arbitrary large) strip region $\Delta_1\mathcal{K}$ which looks as a region of the same type.
The contradiction is only apparent due to the fact that the strip $\Delta_1\mathcal{K}$ is arbitrarily narrow (of order δ) which allows to prove its existence in an easier way, while the width of our final region[22] is of order "$|\lambda_1 - \lambda_0|$" which can be arbitrarily large.
To prove the existence of $\Delta_1\mathcal{K}$ we prove, first, via the local existence theorem, that at least a portion, $\Delta_1^{loc}\mathcal{K}$, of $\Delta_1\mathcal{K}$ exists whose norms satisfy, see figure 7,

$$\mathcal{O} \leq \epsilon_0 \quad , \quad \mathcal{R} \leq \epsilon_0 \quad . \tag{3.11}$$

Second we define λ_* as the sup of all the values $\lambda \in [\lambda_1, \lambda_0]$ such that the portion $\Delta_1\mathcal{K}(\lambda)$ of the strip $\Delta_1\mathcal{K}$ exists satisfying 3.11. We denote this region $\Delta_1\mathcal{K}(\lambda_*)$. Third, using the fact that on $C(\lambda_1, [\nu_*, \nu_* + \delta]) \cup \underline{C}(\nu_*; [\lambda_1, \lambda_*])$, the lower part of the boundary of $\Delta_1\mathcal{K}$, the data are bounded by $c\varepsilon$, we show that in $\Delta_1\mathcal{K}(\lambda_*)$ the norms $\mathcal{O}$ and $\mathcal{R}$ are bounded by $C\varepsilon$. This allows to extend, again via the local existence theorem, the region $\Delta_1\mathcal{K}(\lambda_*)$ in the e_3 direction and prove that,

[22] Either if we consider the first or the second part of our global result.

therefore, λ_* cannot be the sup for all the values $\lambda \in [\lambda_1, \lambda_0]$. To avoid a contradiction, therefore, the whole strip $\Delta_1\mathcal{K} \equiv \Delta_1\mathcal{K}(\lambda_0)$ must exist.
As we said this proof is an easier version of the general one, but the first step is analogous to the one discussed in subsection 3.2 for the general case, namely we prove that in $\Delta_1\mathcal{K}(\lambda_*)$ the following inequalities hold

$$\mathcal{O} \leq C\varepsilon \quad , \quad \mathcal{R} \leq C\varepsilon \ . \tag{3.12}$$

This result is proven with the same strategy used in [Kl-Ni]: assuming first that $\mathcal{O} \leq \epsilon_0$ we prove that the generalized energy norms $\mathcal{Q}$ can be controlled by the same norms on the "initial" boundary of $\Delta_1\mathcal{K}(\lambda_*)$ and therefore bounded by $C\varepsilon$; from these estimates $\mathcal{R} \leq C\varepsilon$ follows. Using this result and the transport equations we show that $\mathcal{O} \leq C\varepsilon$ holds.
To understand where the narrowness of $\Delta_1\mathcal{K}$ is used let us examine in more detail how the first part of this result is obtained namely the proof of the following lemma

Lemma 3.1 *Assume that $\Delta_1\mathcal{K}(\lambda_*)$ be foliated by a double null foliation made by null hypersurfaces which are the level hypersurfaces of two functions $u(p)$ and $\underline{u}(p)$ solutions of the eikonal equation with initial data on $\underline{C}(\nu_*; [\lambda_1, \lambda_*])$ and $C(\lambda_1; [\nu_*, \nu_* + \delta])$ respectively, given by two functions $u|_{\underline{C}(\nu_*;[\lambda_1,\lambda_*])}(p)$ and $\underline{u}_{C(\lambda_1;[\nu_*,\nu_*+\delta])}(p)$ which define on these null hypersurfaces a canonical foliation as discussed in subsection 3.3.1 of* [Kl-Ni]*, see also* [Ni1]*. Then if in $\Delta_1\mathcal{K}(\lambda_*)$ the Riemann norms satisfy $\mathcal{R} \leq c\varepsilon$ it follows that,*

$$\mathcal{O} \leq C\varepsilon \ .$$

Remark: To prove this result we have only to show that the region $\Delta_1\mathcal{K}(\lambda_*)$ can be large in the incoming direction, that is for values of $\lambda > \lambda_1$, while in the outgoing direction as the interval $[\nu_*, \nu_* + \delta]$, can be chosen arbitrarily small, we do not need an extension in that direction. In fact δ can be the variation in ν obtained in the local existence. This implies that all the norm of the not underlined connection coefficients collected in $\mathcal{O}$,[23] can be estimated as in Chapter 4 of [Kl-Ni], but integrating, on the outgoing cones, toward the future direction. This fact, possible for the smallness of δ, makes the proof of the existence of $\Delta_1\mathcal{K}$ a different result than the global one we are looking for. In other words a bootstrap argument is required here only for the e_3 (λ-direction) and not for the e_4 (ν-direction).

Proof: To control the norms of the connection coefficients and their derivatives collected in $\mathcal{O}$ we have to examine their transport equations along the incoming and outgoing (portions of) cones contained in $\Delta_1\mathcal{K}(\lambda_*)$. Those associated to the underlined connection coefficients, along the incoming cones, are exactly of the same type as the corresponding ones in Chapter 4 of [Kl-Ni]. Those associated to the ("small" portions of) outgoing cones allow to obtain the norms of the non underlined connection coefficients as an integral along the portions of the

[23] recall that in $\mathcal{O}$ there are also the norms of the underlined connection coefficients.

outgoing cones plus their initial value on $\underline{C}(\nu_*; [\lambda_1, \lambda_*])$. These last estimates differ from the corresponding ones of Chapter 4 of [Kl-Ni] where the integrations are done, using the transport equations along the "outgoing cones", starting from above and going down backward in time.
The choice of integrating along the outgoing "cones" from the above is necessary in the global existence proof of [Kl-Ni] to obtain the right decay factors, but in the present situation, due to the smallness od δ we can, and have to, proceed in the opposite way.
To clarify this point let us recall the logic for the estimates of the $\mathcal{O}$ and $\mathcal{R}$ norms used in [Kl-Ni]. This is basically the content of Chapter 4; the main assumption is that there exists a spacetime region where $\mathcal{O}$ and $\mathcal{R}$ are bounded by ϵ_0. This assumption done, one proves that $\mathcal{O}$ and $\mathcal{R}$ are in fact bounded by $C\varepsilon$ where ε indicates the smallness of initial data and can be chosen sufficiently small so that $C\varepsilon \leq \frac{1}{2}\epsilon_0$. The estimates for $\mathcal{R}$ are obtained once we control the $\mathcal{Q}$ norms in terms of the same norms on the "initial" boundary of $\Delta_1\mathcal{K}(\lambda_*)$ and the assumption $\mathcal{O} \leq \epsilon_0$. The estimates for $\mathcal{O}$ are obtained using the bound $\mathcal{R} \leq C\varepsilon$ the transport equations and the estimates $\mathcal{O} \leq C\varepsilon$ on the $\underline{C}(\nu_*; [\lambda_1, \lambda_*])$ part of the $\Delta_1\mathcal{K}(\lambda_*)$ boundary.

The main difference with the general case is in the estimate for $\mathcal{Q}$. This is achieved through a volume integration on the whole region which allows to control the $\mathcal{Q}$ integrals on the "upper" boundaries in terms of those along the "lower" ones plus some volume integrals denoted "error terms". Estimating the "error terms", one can show that they are $O(\epsilon_0^2)$, using the previous assumptions on $\mathcal{O}$ and $\mathcal{R}$, therefore showing that the integral norms $\mathcal{Q}$ can be bounded in terms of the same norms made with the initial data and, therefore, by $C\varepsilon$. In the [Kl-Ni] two conditions are required to prove these steps: the correct asymptotic decay and the correct regularity of the various connection coefficients.[24] As said before, in the present case, due to the fact that the $\Delta_1\mathcal{K}$ regions are "narrow" the decay is not important in the outgoing direction and we can integrate from below. This has also the (crucial) side effect that, as on the "lower" boundary of $\Delta_1\mathcal{K}$ a canonical foliation has already been established, the needed regularity of the various connection coefficients and Riemann components is immediately obtained.[25] The discussion for $\Delta_2\mathcal{K}$ is exactly the same with the obvious interchanges and we do not repeat it here.

[24] The second requirement arises from the fact that the the connection coefficients have to be controlled up to third order, for controlling the Riemann tensor up to second order; this implies that to achieve the result the estimate of the n-order derivatives of the connection coefficients must require only the control of the $n-1$-order for the Riemann tensor. This is the reason why we need the so called "last canonical foliation" procedure, see the detailed dicussion in [Kl-Ni].

[25] If this were not the case we should have to assume that on the "upper boundary" of $\Delta_1\mathcal{K}$ a canonical foliation is given, but this requires having on it already a background foliation with the appropriate estimates for $\mathcal{R}$ and $\mathcal{O}$ ($\leq \epsilon_0$). These estimates cannot be obtained if the region is not narrow due to the lack of the right regularities relations between the $\mathcal{O}$ coefficients and the $\mathcal{R}$ components. A canonical foliation on the "last slice" could be assumed as in the general proof, but then one should again prove a bootstrap argument also in the ν direction requiring again a semilocal extension and so on and so for.

3.3.2 $\Delta_3\mathcal{K}$

The existence proof for the region $\Delta_3\mathcal{K}$ is simpler as it is strictly a local existence proof. In fact this region is the maximal development of the null surface $C(\overline{\lambda}(\nu_*);[\nu_*,\nu_*+\delta])\cup\underline{C}(\nu_*;[\overline{\lambda}(\nu_*),\overline{\lambda}(\nu_*+\delta)])$ which can be made as small as we like just decreasing the parameter δ. Again on this surface one has to build a canonical foliation exactly following the strategy described in [Kl-Ni] and [Ni1].

3.4 The regularity of the initial data

In this subsection we determine the minimum regularity of the initial data required to achieve our existence proof. Here the situation is more complicated than in the non characteristic case, studied in [Ch-Kl] and [Kl-Ni], due to the presence of the "loss of derivatives" phenomenon discussed in (I), see also [Mu] for the local existence result, which implies that a greater regularity is needed. The basic fact to determine the due regularity for the initial data is that to prove the global existence result we have to control in the $L^2(C)$ norms,[26] in the bulk region, up to second derivatives of the Riemann tensor and third derivatives of the connection connections, in other words up to $s=4$ derivatives of the metric components.
Fixed s for the spacetime Sobolev norms, the local existence theorem or more precisely the costraints on the initial data for the characteristic local existence, see [Mu], imply that the angular derivatives of the initial data metric components must be controlled up to order $2s-1$. The same result we obtain here as we are going to discuss in some detail.
In subsection 3.1.1 of (I) we showed how the C^α regularities of the various connection coefficients and the null Riemann components are connected; to adapt it to the Sobolev case we proceed as follows:
From (I) we have on C_0

$$\begin{aligned}&\Omega,\ \gamma,\ \chi,\ \omega,\ \not{\mathbf{D}}_4\hat{\chi}\in C^{q'}(S)\\ &X,\ \zeta,\ \not{\nabla}\log\Omega\in C^{q'-1}(S)\\ &\underline{\chi},\ \underline{\omega}\in C^{q'-2}(S)\ \ .\end{aligned}\tag{3.13}$$

and from the regularity of the metric components and the connection coefficients we have immediately, see (I) for more details,

$$\alpha\in C^{q'}(S)\ ,\ \beta\in C^{q'-1}(S)\ ,\ (\rho,\sigma)\in C^{q'-2}(S)\ ,\ \underline{\beta}\in C^{q'-3}(S)\ .\tag{3.14}$$

As we will impose the needed regularity in terms of the $H^s_p(S)$ norms, [27] conditions 3.13, 3.14 can be reexpressed in the following way, with $p\in[2,4]$,

$$\Omega,\ \gamma,\ \chi,\ \omega,\ \not{\mathbf{D}}_4\hat{\chi}\in H^{q'+1}_p(S)$$

[26] Here C is a null incoming or outgoing cone of the double null canonical foliation.

[27] Recall that $\sup_S|G|\leq cr^{-\frac{1}{2}}\|G\|_{H^1_4(S)}$, see [Kl-Ni], Lemma 4.1.3.

$$X,\ \zeta,\ \nabla\!\!\!/\log\Omega \in H_p^{q'}(S)\ \ ,\ \ \underline{\chi},\ \underline{\omega} \in H_p^{q'-1}(S) \tag{3.15}$$
$$\alpha \in H_p^{q'+1}(S)\ ,\ \beta \in H_p^{q'}(S)\ ,\ (\rho,\sigma) \in H_p^{q'-1}(S)\ ,\ \underline{\beta} \in H_p^{q'-2}(S)\ .$$

To determine the minimum value of q' let us consider the connection coefficient $\underline{\hat{\chi}}$ and observe that from the explicit expression of $\underline{\beta}$,

$$\underline{\beta} = -[\nabla\!\!\!/ \mathrm{tr}\underline{\chi} - d\!\!\!/\mathrm{iv}\,\underline{\chi} + \zeta\cdot\underline{\chi} - \zeta\mathrm{tr}\underline{\chi}]\ ,$$

it follows that $\underline{\beta} = O(\nabla\!\!\!/\underline{\hat{\chi}}) + \textit{other terms}$. From the explicit expression of the norms $\mathcal{R}$, see the appendix, it follows that on the spacetime and, therefore, on C_0 the following norm has to be bounded and small:

$$\|\mathbf{D}\!\!\!/_3^2\underline{\beta}\|_{L^2(C_0)} = O(\epsilon_0)\ \ \text{which implies}\ \ \|\mathbf{D}\!\!\!/_3^2\nabla\!\!\!/\underline{\hat{\chi}}\|_{L^2(C_0)} = O(\epsilon_0)\ . \tag{3.16}$$

Due to the loss of derivatives this implies, at its turn, that on C_0 we must have also

$$\|\nabla\!\!\!/^5\underline{\hat{\chi}}\|_{L^2(C_0)} = O(\epsilon_0)\ . \tag{3.17}$$

As we impose the initial conditions in terms of the $H_p^s(S)$ norms, 3.17 is satisfied requiring

$$\|\nabla\!\!\!/^5\underline{\hat{\chi}}\|_{H_p^0(S)} = O(\epsilon_0) \text{ which also implies } \|\underline{\hat{\chi}}\|_{H_p^5(S)} = O(\epsilon_0)\ , \tag{3.18}$$

where we always ignored the appropriate weights, $r^{(\alpha-\frac{2}{p})}$, of the norms. Condition 3.18 compared with 3.15 gives $q'-1=5$ and therefore

$$\begin{aligned}&\Omega,\ \gamma,\ \chi,\ \omega,\ \mathbf{D}\!\!\!/_4\hat{\chi} \in H_p^7(S)\\ &X,\ \zeta,\ \nabla\!\!\!/\log\Omega \in H_p^6(S)\ \ ,\ \ \underline{\chi},\ \underline{\omega} \in H_p^5(S)\\ &\alpha \in H_p^7(S)\ ,\ \beta \in H_p^6(S)\ ,\ (\rho,\sigma) \in H_p^5(S)\ ,\ \underline{\beta} \in H_p^4(S)\ .\end{aligned} \tag{3.19}$$

In conclusion the minimum value of q in $J^{(q)}_{C_0\cup\underline{C}_0}$, see 2.2, is $q=7$.

Remarks:

a) Observe that the requirement $q=7$ is connected, as we said, to the characteristic constraint equations which implies the so called "loss of derivatives" and also to the Bianchi equations. In fact let us consider the null Riemann component

$$\alpha = -[\mathbf{D}\!\!\!/_4\hat{\chi} + \mathrm{tr}\chi\hat{\chi} - (\mathbf{D}_4\log\Omega)\hat{\chi}]\ ;$$

From the explicit expression of $\mathcal{R}$ it follows that we have to require that

$\|\mathbf{D}\!\!\!/_3^2\alpha\|_{L^2(C_0)} = O(\epsilon_0)$ implying, proceeding as before, $\|\nabla\!\!\!/^4\hat{\chi}\|_{L^2(C_0)} = O(\epsilon_0)$.

Again this is satisfied imposing

$$\|\nabla\!\!\!/^4\hat{\chi}\|_{H_p^0(S)} = O(\epsilon_0)\ \ \text{which requires}\ \ \|\hat{\chi}\|_{H_p^4(S)} = O(\epsilon_0)\ . \tag{3.20}$$

To satisfy this bound it would be enough to choose $q' = 3$, implying $q = 4$ instead of $q = 7$. Nevertheless this would not be sufficient as the Bianchi equations in the outgoing direction imply that if $\alpha \in H^4_p(S)$ then $\underline{\beta} \in H^1_p(S)$, while we know that we have to control $\|\underline{\beta}\|^4_p(S)$.

b) The function of the initial data $J^{(q)}_{C_0 \cup \underline{C}_0}$ which we impose to be small, is a function of the $|\cdot|_{p,S}$ norms. Nevertheless the initial data smallness could also be prescribed in terms of the $H^s(C)$ norms. We could also in this case require $s = 7$ and this would imply less regularity for the initial data, but we will not discuss this aspect any further here.

4 The existence proof for the last slice canonical foliation

In this section we discuss in which part of the boundaries of the different regions a canonical foliation has to be imposed. This has been claimed many times and we make now these statements more precise.
We do not give here the definition of a canonical foliation of a null hypersurface; the reader can find it, in any detail, in [Kl-Ni], Chapter 4, and in [Ni1]. Either we do not discuss why these foliations are needed, but we only recall that they allow to control the estimates of the $n + 1$ derivatives of the connection coefficients in terms of the estimates for the n derivatives of the Riemann tensor, see Lemma 3.1 and footnote 22. This is a crucial step for the implementation of the bootstrap argument, proving Theorem 3.2.

That (part of) the boundaries of the various regions have to be canonically foliated is required in various occasions, more precisely:

i) In the definition of $\mathcal{K}(\tau)$ the portion $C(\lambda_1; [\nu_0, \overline{\nu}]) \cup \underline{C}(\overline{\nu}; [\lambda_1, \overline{\lambda}])$ of the boundary has to be foliated with a canonical foliation.

ii) The proof that the region $\mathcal{K}(\tau_*)$ can be extended to $\mathcal{K}(\tau_* + \delta)$, requires that this extension has the same properties of $\mathcal{K}(\tau)$. Recalling that

$$\mathcal{K}(\tau_* + \delta) = \mathcal{K}(\tau_*) \cup \Delta_1\mathcal{K} \cup \Delta_2\mathcal{K} \cup \Delta_3\mathcal{K} \tag{4.1}$$

this implies that part of the boundary of $\Delta_1\mathcal{K}$ has to be canonically foliated. Observe that

$$\begin{aligned} \partial\Delta_1\mathcal{K} \;=\; & C(\lambda_1; [\nu_*, \nu_* + \delta]) \cup \underline{C}(\nu_*; [\lambda_1, \overline{\lambda}(\nu_*)]) \cup C(\overline{\lambda}(\nu_*); [\nu_*, \nu_* + \delta]) \\ & \cup \underline{C}(\nu_* + \delta; [\lambda_1, \overline{\lambda}(\nu_*)]) \;, \end{aligned} \tag{4.2}$$

therefore to make the spacetime $\mathcal{K}(\tau_* + \delta)$ fulfilling all the requested conditions, the portion $C(\lambda_1; [\nu_*, \nu_*+\delta]) \cup \underline{C}(\nu_*+\delta; [\lambda_1, \overline{\lambda}(\nu_*)])$ of $\partial\Delta_1\mathcal{K}$ has to be canonically foliated. Remark that, nevertheless, to prove the existence of $\Delta_1\mathcal{K}$ it is enough to have a canonical foliation on $C(\lambda_1; [\nu_*, \nu_* + \delta])$.[28] The canonical foliation on

[28] As for the smallness of δ in $\Delta_1\mathcal{K}$ we can integrate toward the future in the outgoing direction, it is enough that a canonical foliation be present on $\underline{C}(\nu_*; [\lambda_1, \overline{\lambda}(\nu_*)])$.

$\underline{C}(\nu_* + \delta; [\lambda_1, \overline{\lambda}(\nu_*)])$ has to be built after the region $\Delta_1\mathcal{K}$ has been obtained and it is only required to have the region $\mathcal{K}(\tau_* + \delta)$ with the right properties, i),..., vi), of Section 2.
The situation is quite similar for the region $\Delta_2\mathcal{K}$; to prove its existence the only part of the boundary which has to be canonically foliated is $\underline{C}(\nu_*; [\overline{\lambda}(\nu_*), \overline{\lambda}(\nu_*) + \delta])$. In fact it is clear that on $C(\overline{\lambda}(\nu_*); [\nu_0, \nu_*])$ the foliation induced from the incoming "cones" starting from the canonical foliation defined on $C(\lambda_1; [\nu_0, \nu_*])$ is already canonical.[29]
Finally the existence proof of the region $\Delta_3\mathcal{K}$ is only a local problem. Therefore it requires only that the lower part of its boundary has the right properties. For $C(\overline{\lambda}(\nu_*); [\nu_*, \nu_* + \delta])$ this follows from the canonical foliation of $C(\lambda_1; [\nu_*, \nu_* + \delta])$ and for $\underline{C}(\nu_*; [\overline{\lambda}(\nu_*), \overline{\lambda}(\nu_*) + \delta])$ from the requirement which has been satisfied in the construction of $\Delta_2\mathcal{K}$. Again, once $\Delta_3\mathcal{K}$ has been obtained, a canonical foliation has to be imposed on $\underline{C}(\nu_* + \delta; [\overline{\lambda}(\nu_*), \overline{\lambda}(\nu_*) + \delta])$.[30]
This completes the description of how the canonical foliation has to be placed on the various null hypersurfaces. The existence proof of these foliations is in [Ni1] and looking at the various steps of the construction of the various regions involved and to the initial data conditions it is easy to realize that the assumptions required in this proof are always satisfied.

Remark: As already said, imposing on the boundary a canonical foliation is done for being able to control, in the spacetime, the $n + 1$ derivatives of the connection coefficients in terms of the n derivatives of the Riemann tensor, avoiding any loss of derivatives in the spacetime. As, on the other side, the loss of derivatives on the initial hypersurfaces, due to their characteristic nature, is inavoidable and force us to require a greater regularity on $C_0 \cup \underline{C}_0$ than the one needed in the spacetime interior, it follows that, in principle, we could avoid the request of having a canonical foliation on C_0.

5 The local existence result

In this section we give some hints about the local existence result we need to complete our global proof and which has been stated in Section 3, Theorem 3.1. We do not present here the details of the proof, we describe only two different procedures to achieve the result. The reason is twofold, first there are in the literature various proofs basically fulfilling our goal, in particular we refer to those of A.Rendall, [Ren], H.Muller Zum Hagen, [Mu] and M.Dossa, [Do]; second in a subsequent paper one of the authors (F.N.) will present a new proof of the local existence result based on a Cauchy-Kowalevski type argument, [Ni2].

Assume we want to use the work of A.Rendall, [Ren] or the one of H.Muller Zum Hagen [Mu]. The main difficulty in adapting these results to our case is

[29] A slight difference in the "semilocal" existence proof for this region is that in this case the assumptions for the regions $\Delta_2\mathcal{K}(\nu)$ require that the portion of its boundary, $\underline{C}(\nu; [\overline{\lambda}(\nu), \overline{\lambda}(\nu) + \delta])$, has to be canonically foliated.

[30] Once $\Delta_1\mathcal{K}$ and $\Delta_3\mathcal{K}$ are obtained, the procedure will be to impose a canonical foliation on the whole $\underline{C}(\nu_* + \delta; [\lambda_1, \overline{\lambda}(\nu_*) + \delta])$.

that they have been obtained using harmonic coordinates while we want that the "gauge" for $\mathcal{K}(\tau)$ be the one associated to the double null canonical foliation, we called in (I) "Ω-gauge". This requires to state precisely the connection between the initial data written in these two different gauges so that we can reexpress their results in our formalism.

5.0.1 The relation between the harmonic and the Ω-foliation gauges.

This has been discussed in great detail in (I), here we just recall the rational behind it. In (I) the initial data are given on two null hypersurfaces foliated by two dimensional surfaces S^2-diffeomorphic. They are expressed in terms of connection coefficients which are tensors on the leaves of these foliations and of the metric defined on them. The way they have to be assigned, to satisfy the costraints, has been discussed in (I). On the other side as the local existence result has been proved in the harmonic gauge, we have to express our data in this gauge. This is the content of subsection 4.1 of (I). Once this has been done we are allowed to use the harmonic local existence result.
Nevertheless the goal in not yet achieved as in the local result obtained, for instance in [Mu], the region whose existence is proved is foliated by spacelike hypersurfaces defined as level hypersurfaces of a time function $\tau(p)$ which, if the initial data are "small", approximate the portion of t-constant hyperplanes intersecting the region inside the null initial hypersufaces. Therefore to obtain the local region we need to complete this result adding to this region the local region which is the maximal development of the "data" on the last τ-leave of the previous local result. In this way a small "diamond"-shaped region is built and, finally, the proof that in this region the norms $\mathcal{R}$ and $\mathcal{O}$ are bounded by ϵ_0 goes as discussed before.
The construction of the local solution envisaged now can be avoided just trying to get a local solution proceeding in a more straightforward way from the Einstein equations written in the "Ω-gauge". The basic idea is to write those structure equations for the connection coefficients which are evolution equations along a null direction, for instance the incoming one, see equations (1.8), (1.10), (1.17), (1.18), (1.20) of (I), together with the equations defining them in terms of the derivatives of the metric tensor γ_{ab}. The solutions of this set of equations satisfying also the set of equations associated to the structure equations along the outgoing direction are solutions of the vacuum Einstein equations. One could, therefore, obtain a real analytic solution applying the Cauchy-Kowalevski result to the characteristic case, see [Du], and then look for a less regular (H^s_p) solution as a limit of a sequence of real analytic solutions. Here, nevertheless, a problem arises: to build a sequence of solutions converging in an appropriate norm once the initial data converge to less regular data, we have to use energy-type norms and prove that they are bounded. Using these norms one can show the convergence of a sequence of analytic real solutions. The problem is associated to the fact that the Einstein equations written in the "Ω-gauge" are not of hyperbolic type and therefore we do not have obvious energy norms at our disposal like those used in the harmonic gauge. To overcome this difficulty we

mimic the strategy of [Ch-Kl] and [Kl-Ni] where the energy-type norms used are those made with the Bel-Robinson tensor. We can solve, therefore, this set of equations, applying Cauchy-Kowalevski theorem and then look for a sequence of solutions converging in the appropriate "Bel-Robinson"-energy norms to the (local) solution we are looking for.

6 Appendix

6.1 The $\mathcal{O}$ and the $\mathcal{R}$ norms

Due to the fact that in the characteristic case the regularity required to the initial data is greater than the regularity achieved from the solution we write here the norms which are used for the initial data.

6.1.1 The initial data norms

The initial data norms are regrouped in two sums, one, $J^{(q)}_{C_0}\left[\overline{\gamma}_{ab},\overline{\Omega},\overline{\zeta}_a,\overline{\underline{\chi}},\overline{\underline{\omega}}\right]$, appropriate for the outgoing cone and the second, $J^{(q)}_{\underline{C}_0}\left[\overline{\gamma}_{ab},\overline{\underline{\Omega}},\overline{\underline{X}}^a,\overline{\zeta}_a,\overline{\chi},\overline{\omega}\right]$, for the incoming one. Their explicit expressions were given in (I) and we repeat them here, correcting some misprints,

$$
\begin{aligned}
&J^{(q)}_{C_0}\left[\overline{\gamma}_{ab},\overline{\Omega},\overline{\zeta}_a,\overline{\underline{\chi}},\overline{\underline{\omega}}\right]=\sup_{C_0}\left(r|\overline{\Omega}-\frac{1}{2}|+\frac{r^2}{\log r}|\mathrm{tr}\overline{\chi}-\frac{2}{r}|+r^{(\frac{5}{2}+\delta)}|\hat{\overline{\chi}}|_\gamma\right)+\\
&\sup_{C_0}\left[\left(\sum_{l=1}^{q}|r^{(2+l-\frac{2}{p})}\nabla\!\!\!/^l\mathrm{tr}\chi|_{p,S}+\sum_{l=1}^{q}|r^{(\frac{5}{2}+l+\delta-\frac{2}{p})}\nabla\!\!\!/^l\hat{\overline{\chi}}|_{p,S}+\sum_{l=0}^{q}|r^{(\frac{7}{2}+l+\delta-\frac{2}{p})}\nabla\!\!\!/^l\mathbb{D}_4\hat{\overline{\chi}}|_{p,S}\right.\right.\\
&\left.|r^{(2-\frac{2}{p})}\overline{\omega}|_{p,S}+\sum_{l=1}^{q}|r^{(2+l+\delta-\frac{2}{p})}\nabla\!\!\!/^l\overline{\omega}|_{p,S}\right)+\sum_{l=1}^{q-1}|r^{(1+l+\delta-\frac{2}{p})}\nabla\!\!\!/^l\log\overline{\Omega}|_{p,S}\qquad(6.1)\\
&\left.+\sum_{l=0}^{q-1}|r^{(2+l-\frac{2}{p})}\nabla\!\!\!/^l\overline{\zeta}|_{p,S}+\sum_{l=0}^{q-2}|r^{(2+l-\frac{2}{p})}\nabla\!\!\!/^l\overline{\underline{\omega}}|_{p,S}+\sum_{l=0}^{q-2}|r^{(1+l-\frac{2}{p})}\nabla\!\!\!/^l\overline{\underline{\chi}}|_{p,S}\right]\ .
\end{aligned}
$$

$$
\begin{aligned}
&J^{(q)}_{\underline{C}_0}\left[\overline{\gamma}_{ab},\overline{\underline{\Omega}},\overline{\underline{X}}^a,\overline{\zeta}_a,\overline{\chi},\overline{\omega}\right]=\sup_{\underline{C}_0}\left(r|\overline{\underline{\Omega}}-\frac{1}{2}|+\frac{r^2}{\log r}|\mathrm{tr}\overline{\underline{\chi}}+\frac{2}{r}|+r|\lambda|^{(\frac{3}{2}+\delta)}|\hat{\overline{\underline{\chi}}}|_\gamma\right)+\\
&\sup_{\underline{C}_0}\left[\left(\sum_{l=1}^{q}|r^{(2+l-\frac{2}{p})}\nabla\!\!\!/^l\mathrm{tr}\underline{\chi}|_{p,S}+\sum_{l=1}^{q}||\lambda|^{(\frac{3}{2}+\delta)}r^{(1+l-\frac{2}{p})}\nabla\!\!\!/^l\hat{\underline{\chi}}|_{p,S}\right.\right.\\
&\left.+\sum_{l=0}^{q}||\lambda|^{(\frac{5}{2}+\delta)}r^{(1+l-\frac{2}{p})}\nabla\!\!\!/^l\mathbb{D}_3\hat{\underline{\chi}}|_{p,S}+|r^{(2-\frac{2}{p})}\overline{\underline{\omega}}|_{p,S}+\sum_{l=1}^{q}|r^{(2+l+\delta-\frac{2}{p})}\nabla\!\!\!/^l\overline{\underline{\omega}}|_{p,S}\right)\qquad(6.2)\\
&\left.+\sum_{l=1}^{q-1}|r^{(1+l+\delta-\frac{2}{p})}\nabla\!\!\!/^l\log\overline{\underline{\Omega}}|_{p,S}+\sum_{l=0}^{q-1}|r^{(2+l-\frac{2}{p})}\nabla\!\!\!/^l\overline{\zeta}|_{p,S}+\sum_{l=0}^{q-2}||\lambda|^{\delta}r^{((2-\delta)+l-\frac{2}{p})}\nabla\!\!\!/^l\overline{\omega}|_{p,S}\right.
\end{aligned}
$$

$$+\sum_{l=0}^{q-2}|r^{(1+l-\frac{2}{p})}\nabla\!\!\!/^l\mathrm{tr}\overline{\chi}|_{p,S}+\sum_{l=0}^{q-2}|r^{(2+l-\frac{2}{p})}\nabla\!\!\!/^l\hat{\overline{\chi}}|_{p,S}+\sum_{l=0}^{q-1}|r^{(1+l-\frac{2}{p})}\nabla\!\!\!/^l\underline{\overline{X}}|_{p,S}\Bigg]\ .$$

where $p\in[2,4]$, $\delta>0$ and $q\geq 7$.

Observe that the first sum of norms is denoted by $J^{(q)}_{C_0}\left[\overline{\overline{\gamma}}_{ab},\overline{\Omega},\overline{\zeta}_a,\underline{\overline{\chi}},\underline{\overline{\omega}}\right]$ where not all the quantities appearing in the explicit expression are expressed. In fact we do not write those ones which are obtained on C_0 just deriving along the outgoing direction, mainly χ and ω. The same holds for the second sum with the role of the various quantities interchanged.

6.1.2 The spacetime solution norms

These norms are the same as those used in [Kl-Ni]. We refer therefore, to sections 3.5.2 and 3.5.3, pages 90-95 of this reference.

Acknowledgments: *One of the authors, (F.N.), want to thank P.Chrúshiel, H.Friedich and A.Ashtekar for some interesting discussions. A particular thanks goes also to P.Chrúshiel, H.Friedich and P.Tod for the organization of the semester on "Global Problems in Mathematical Relativity", held at the Isaac Newton Institute for Mathematical Sciences, where part of this work was completed.*
